[Evoked potential - Wikipedia](#)

An evoked potential or evoked response is an electrical potential recorded from the nervous system of a human or other animal following presentation of a stimulus, as distinct from spontaneous potentials as detected by electroencephalography (EEG), electromyography (EMG), or other electrophysiologic recording method.

Evoked potential (EP) tests measure the electrical activity of the brain in response to stimulation of specific sensory nerve pathways. They can detect the slowing of electrical conduction caused by damage (demyelination) along these pathways even when the change is too subtle to be noticed by the

Evoked potentials (EPs), or evoked responses, measure the electrophysiologic responses of the nervous system to a variety of stimuli. In theory, almost any sensory modality can be tested; however, in clinical practice, only a few are used on a routine basis.

[Evoked Potential Tests - Brain and Nerve Tests ...](#)

Evoked potential tests measure the brain's response to stimuli that are delivered through sight, hearing, or touch. These sensory stimuli evoke minute electrical potentials that travel along nerves to the brain, and can be recorded with patch-like sensors (electrodes) that are attached to the scalp and skin over various peripheral sensory nerves.

[Visual Evoked Potentials \(VEP\)](#) This test records the response of the brain's visual centre to a checkerboard picture or flashing light. This test checks the visual pathway and ensures that the brain is receiving information about what we see.

Multiple Sclerosis Evoked Potentials Testing and Diagnosis

What is an evoked potentials study? Evoked potentials studies measure electrical activity in the brain in response to stimulation of sight, sound, or touch. Stimuli delivered to the brain through each of these senses evoke minute electrical signals. These signals travel along the nerves and through
